Endorphins (contracted from "endogenous morphine")

Are endogenous opioid neuropeptides and peptide hormones in humans and other animals. They are produced by the central nervous system and the pituitary gland. The term "endorphins" implies a pharmacological activity (analogous to the activity of the corticosteroid category of biochemicals) as opposed to a specific chemical formulation. It consists of two parts: endo- and -orphin; these are short forms of the words endogenous and morphine, intended to mean "a morphine-like substance originating from within the body".^[3] This class of endorphins includes three compounds— α -endorphin (α -opiendorphins), β -endorphin (β -opiendorphins), and γ -endorphin (γ -opiendorphin) which preferentially bind to μ -opioid receptors.^[4] The principal function of endorphins is to inhibit the communication of pain signals; they may also produce a feeling of ~~joy~~ very similar to that produced by other opioids.
